But very valuable “interest graph”

# Part I: Network Structure

# What can networks tell us?

- The strength of weak ties [Granovetter '73]
  - How do people find new jobs?
  - Friends and acquaintances
  - Surprising fact: discovery is enabled by weak ties

# Strength of weak ties

- Definition: a *bridge* in a graph is an edge whose removal disconnects the endpoints.

# Strength of weak ties

- Definition: a *local bridge* in a graph is an edge whose endpoints have no common neighbor.

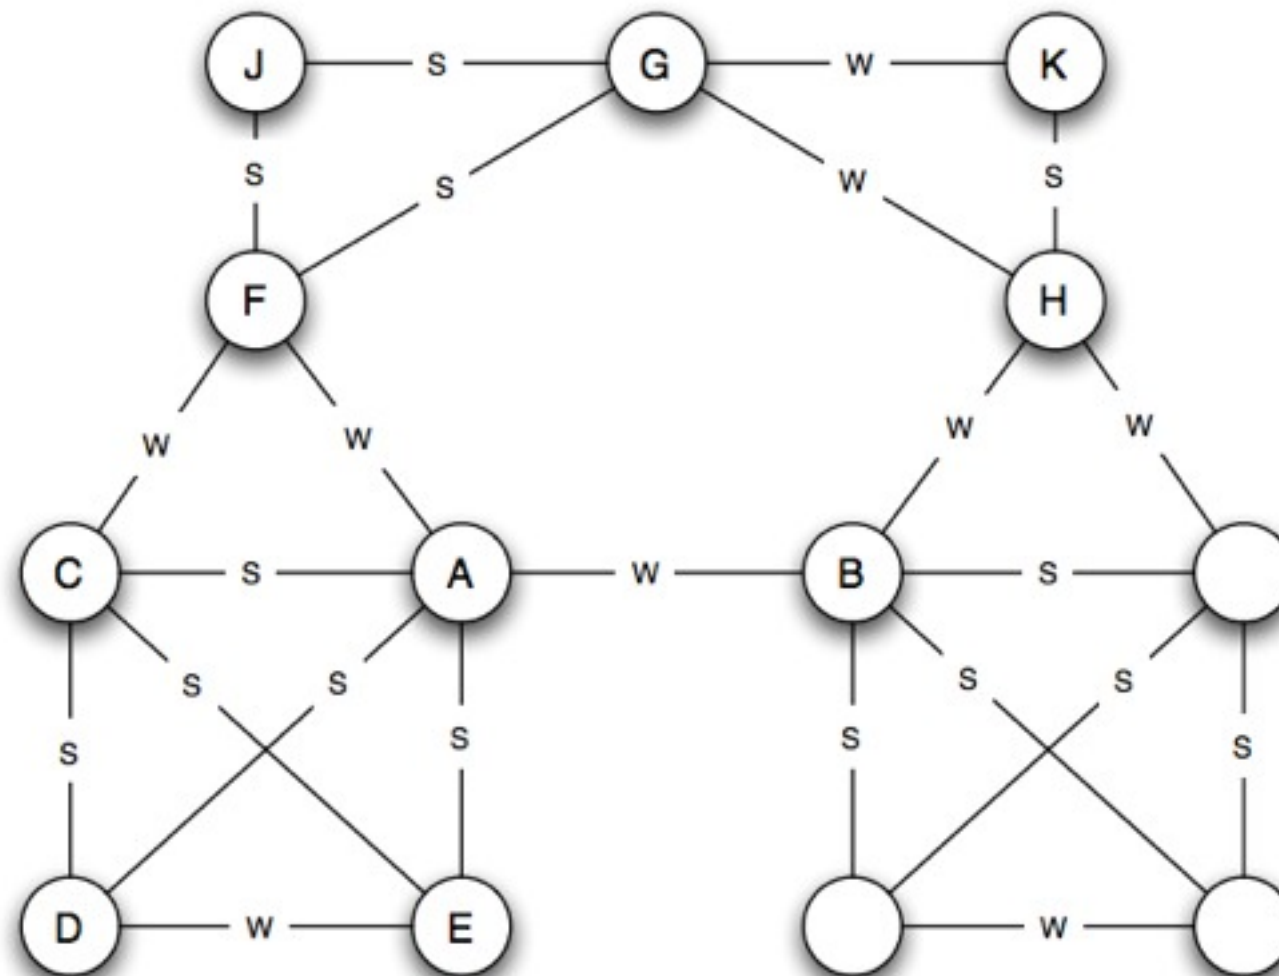

# Triadic closure

# Strong Triadic closure

**Strong Triadic Closure Property:** if the node has strong ties to two neighbors, then these neighbors must have at least a weak tie between them.

# Strength of Weak Ties

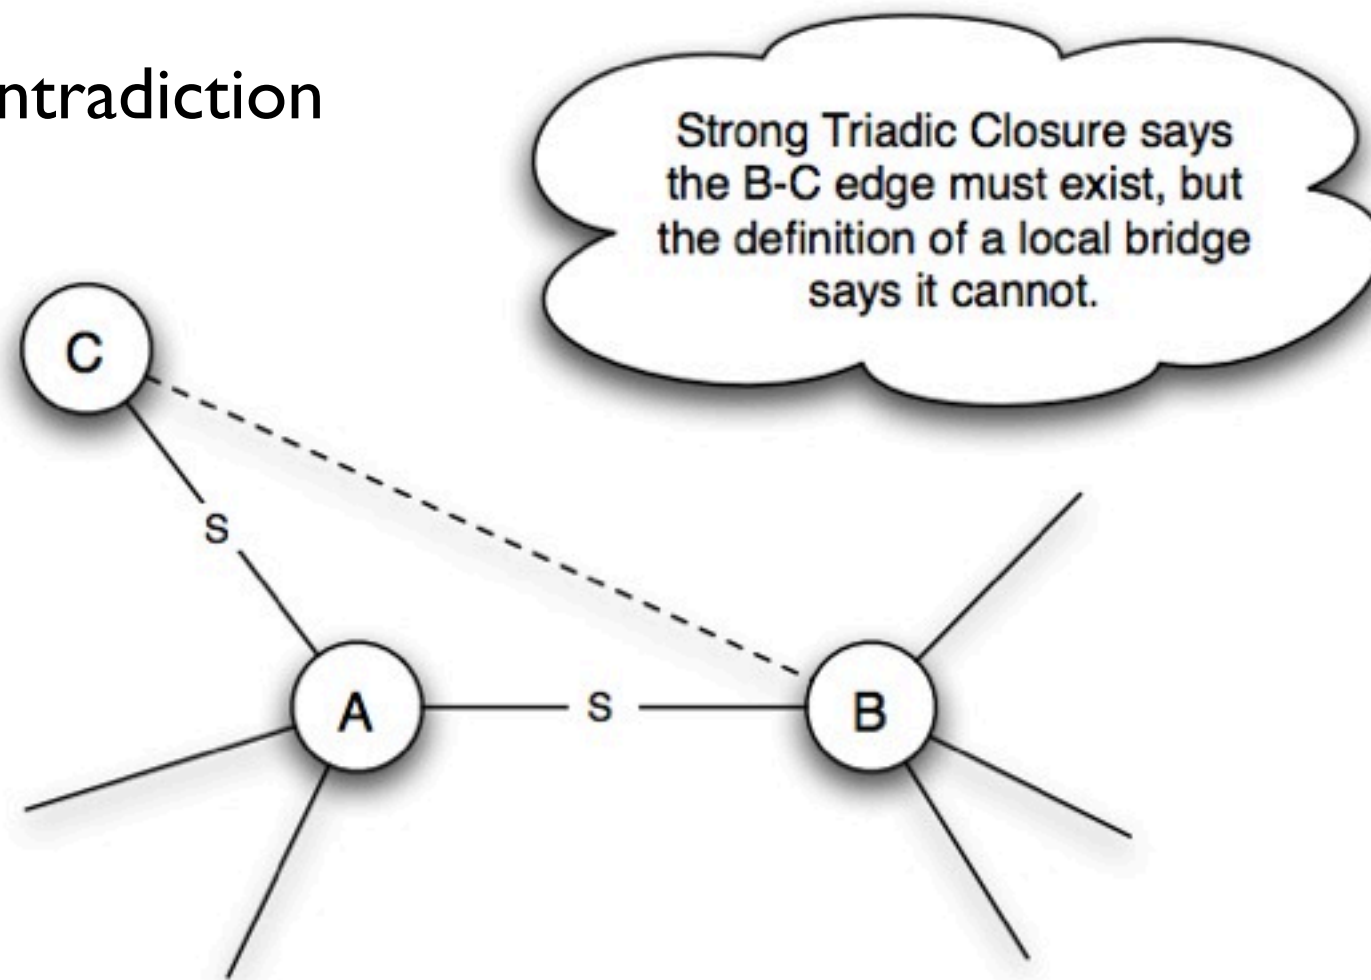

Claim: If a node  $A$  in a network satisfies the Strong Triadic Closure Property and is involved in at least two strong ties, then any local bridge it is involved in must be a weak tie.

Consequence: all local bridges are weak ties!

# Strength of Weak Ties

Claim: If a node A in a network satisfies the Strong Triadic Closure Property and is involved in at least two strong ties, then any local bridge it is involved in must be a weak tie.

Proof: by contradiction

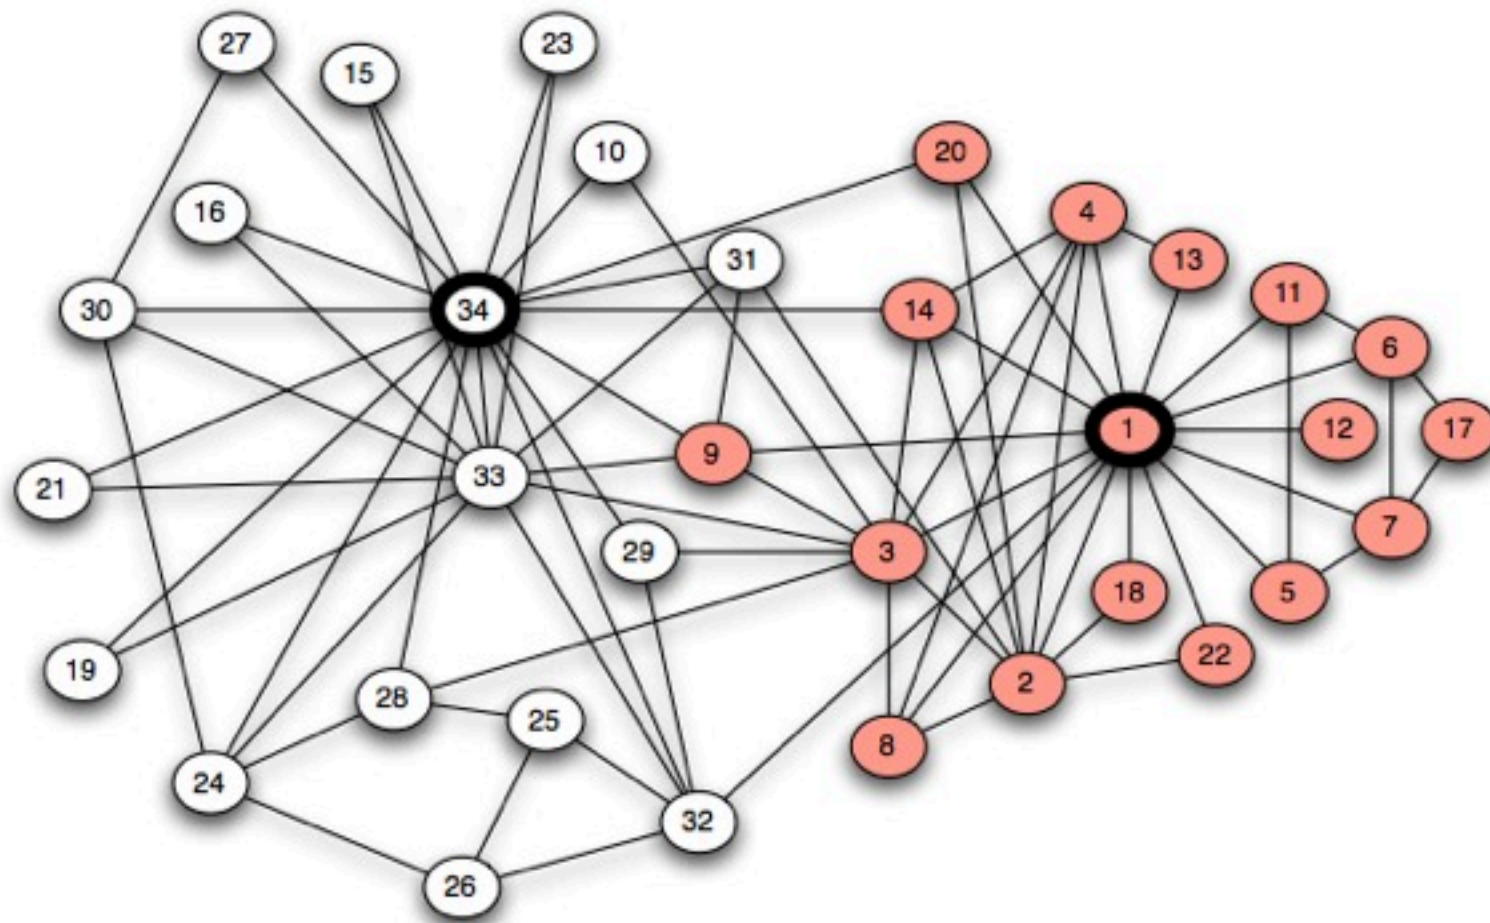

# Strength of Weak Ties

- Discovery is enabled by weak ties
  - Surprising strength of weak ties!
- Simple structural model explains this cleanly
- Similar observations for Twitter/Facebook

# More network insights

- Zachary's karate club and graph partitioning

# Six degrees of separation

- Milgram's experiment:
  - How are people connected?
  - Letters given to people in Omaha
  - Target is a person in Boston
  - Rule: can only forward letters to people  
\*you know\* ( $\leq$  social network)
  - How many hops did it take?

# Milgram's experiment

# Six degrees of separation

- Bacon number game

- Short paths exist, and abound!

# How?

- The world seems to be small
- But how does this happen?

# How?

# Watts-Strogatz model

- Each node forms 2 links:
  - All nodes within  $r$  hops
  - $k$  nodes picked uniformly at random

# Watts-Strogatz model

- Property: short paths exist between everyone!
- Intuition: random links exponentiate due to lack of triangles

# Decentralized search

- Is Milgram's experiment now explained?
  - Watts-Strogatz: short paths exist
  - But how can we possibly navigate?

# Milgram's experiment

# Watts-Strogatz revisited

- Navigate using only local information
- Impossible to navigate in this world!
  - So does *not* explain Milgram's experiment
  - Intuition: random links are *too* random

# Kleinberg's model

- Slight change: given exponent  $q$ , for nodes  $u, v$  create a link with probability  $d(u, v)^{-q}$

(a) A small clustering exponent

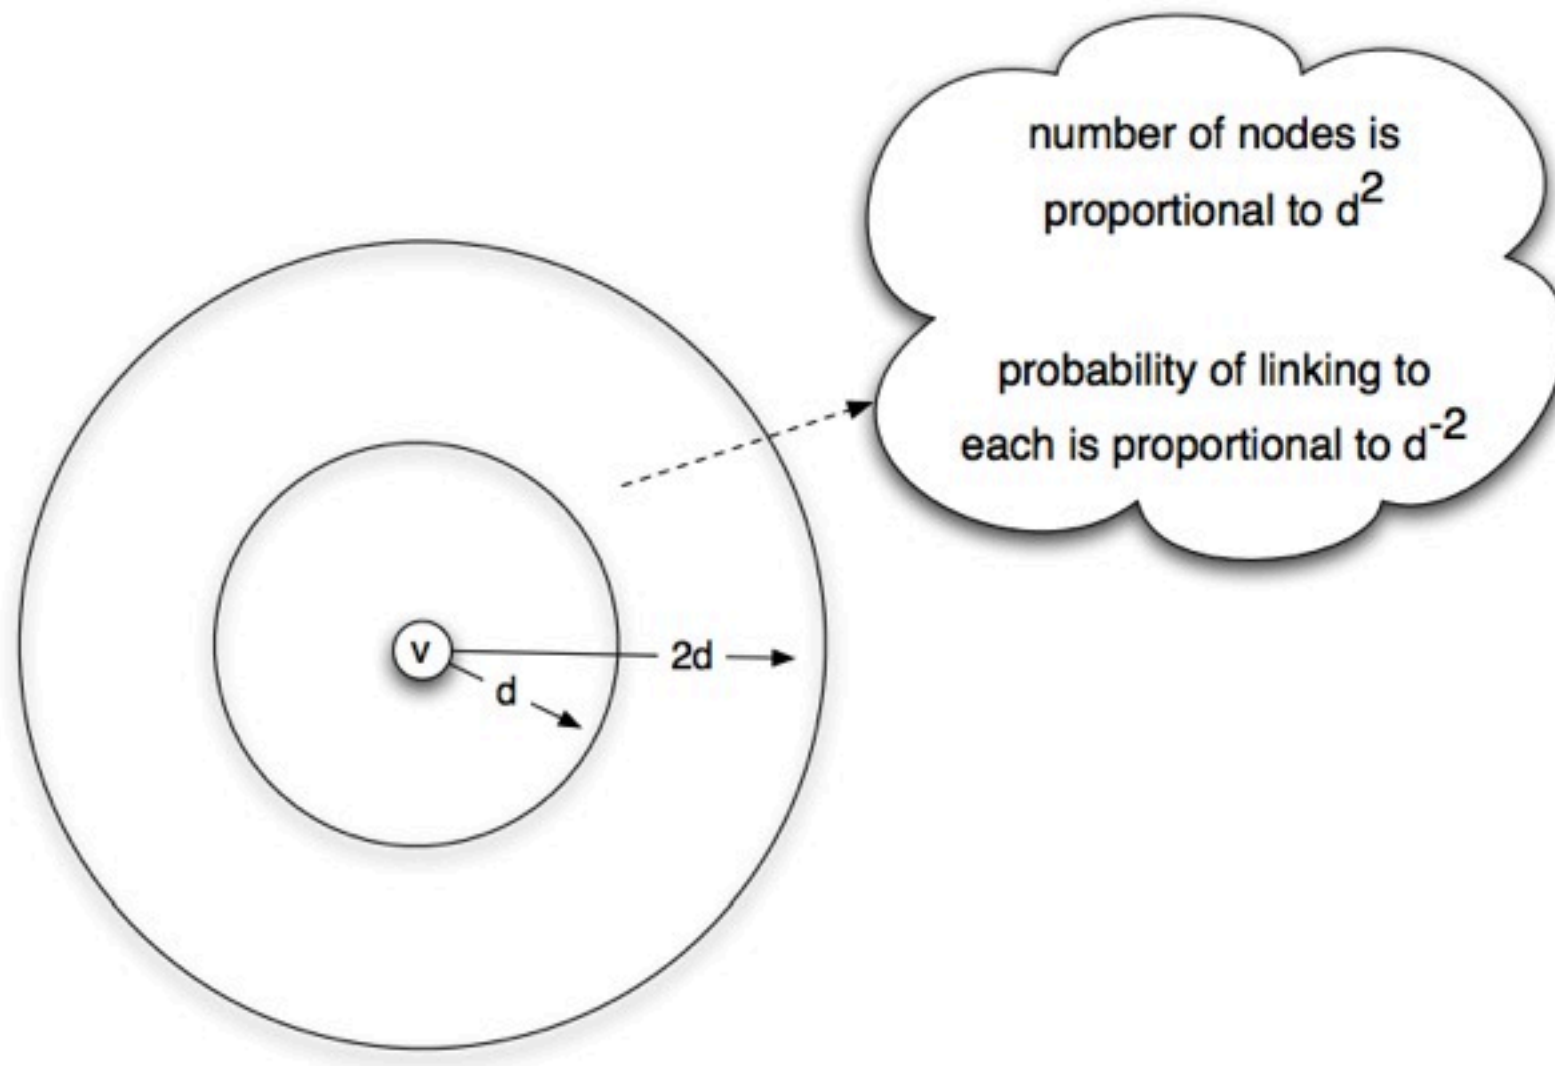

(b) A large clustering exponent

# Kleinberg's model

# Kleinberg's model

- Some intuition:

# Network structure

- Understanding structure affords deep insights
- Interplay between sociology and graph theory

# Part II: Applications

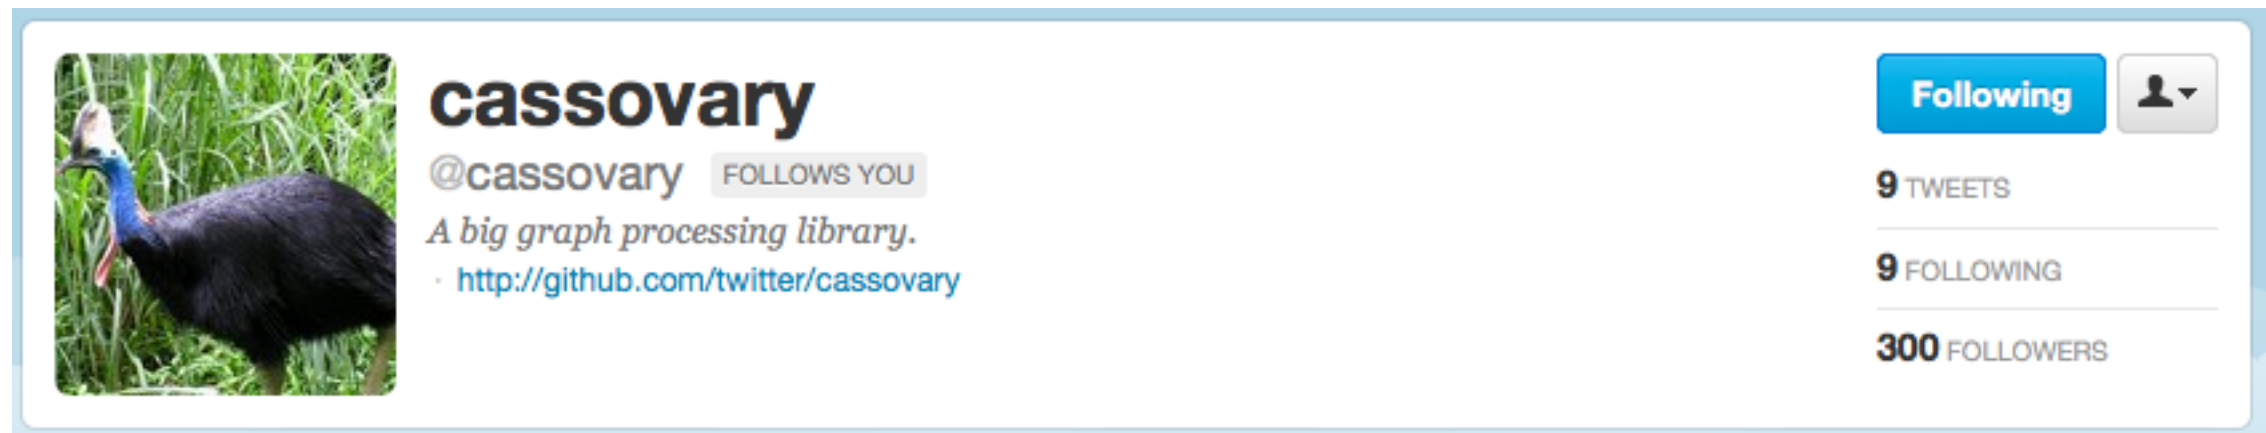

# Part II: Applications

- Recommendations

# Graph Engine: Cassovary

In-memory computation

No compression!

Adjacency list format

Open source: <https://github.com/twitter/cassovary>

# Link Prediction

- General algorithms:
  - Most popular in a country
  - Popular movie stars, pop stars, etc
- Personalized algorithms
  - Triadic closure
  - Personalized pagerank
  - SALSA
- Data: Social graph + usage (relationship strength, interests)

Follow

# The Long Tail

# Pagerank

- Start with equal weights on every node
- Distribute weight equally among outgoing edges

# Pagerank

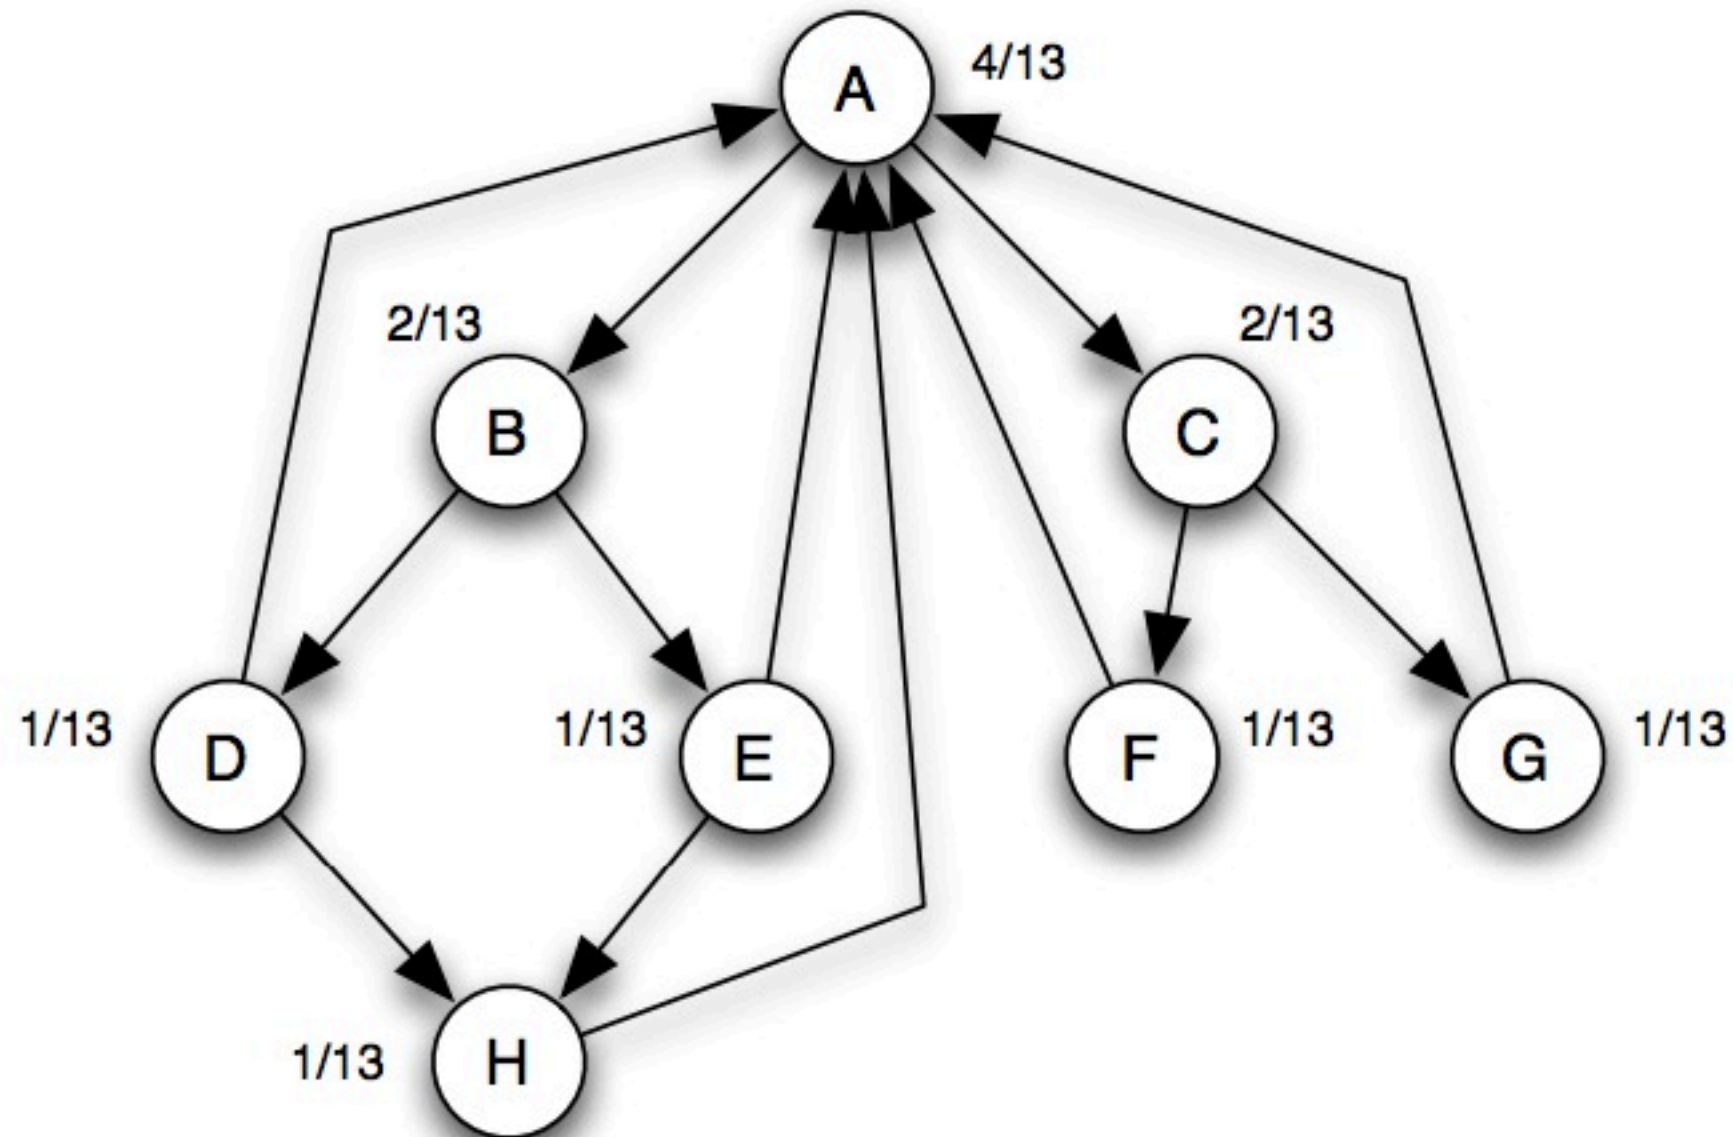

# Pagerank

$$1/16 + 1/16 + 1/8 + 1/8 + 1/8 = 1/2$$

# Pagerank

# Pagerank

- Alternate matrix formulation:
  - Adjacency matrix  $A$

$$\begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

# Pagerank

- Alternate matrix formulation:
  - Adjacency matrix  $A$  (*normalized*)

$$\begin{bmatrix} 1/4 & 1/4 & 1/4 & 1/4 \end{bmatrix} \cdot \begin{bmatrix} 0 & 1/2 & 0 & 1/2 \\ 0 & 0 & 1/2 & 1/2 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} = \begin{bmatrix} 1/4 & 1/8 & 3/8 & 1/4 \end{bmatrix}$$

# Pagerank

- Matrix view:

$$\pi^t \cdot A = \pi^{t+1}$$

$$\pi^0 \cdot A^t = \pi^t$$

- Convergence via Eigenvectors:

$$\bar{\pi} \cdot A^t = \bar{\pi}$$

# Personalized-pagerank

- A personalized version of pagerank
  - Reset to source  $u$  with probability  $\lambda$

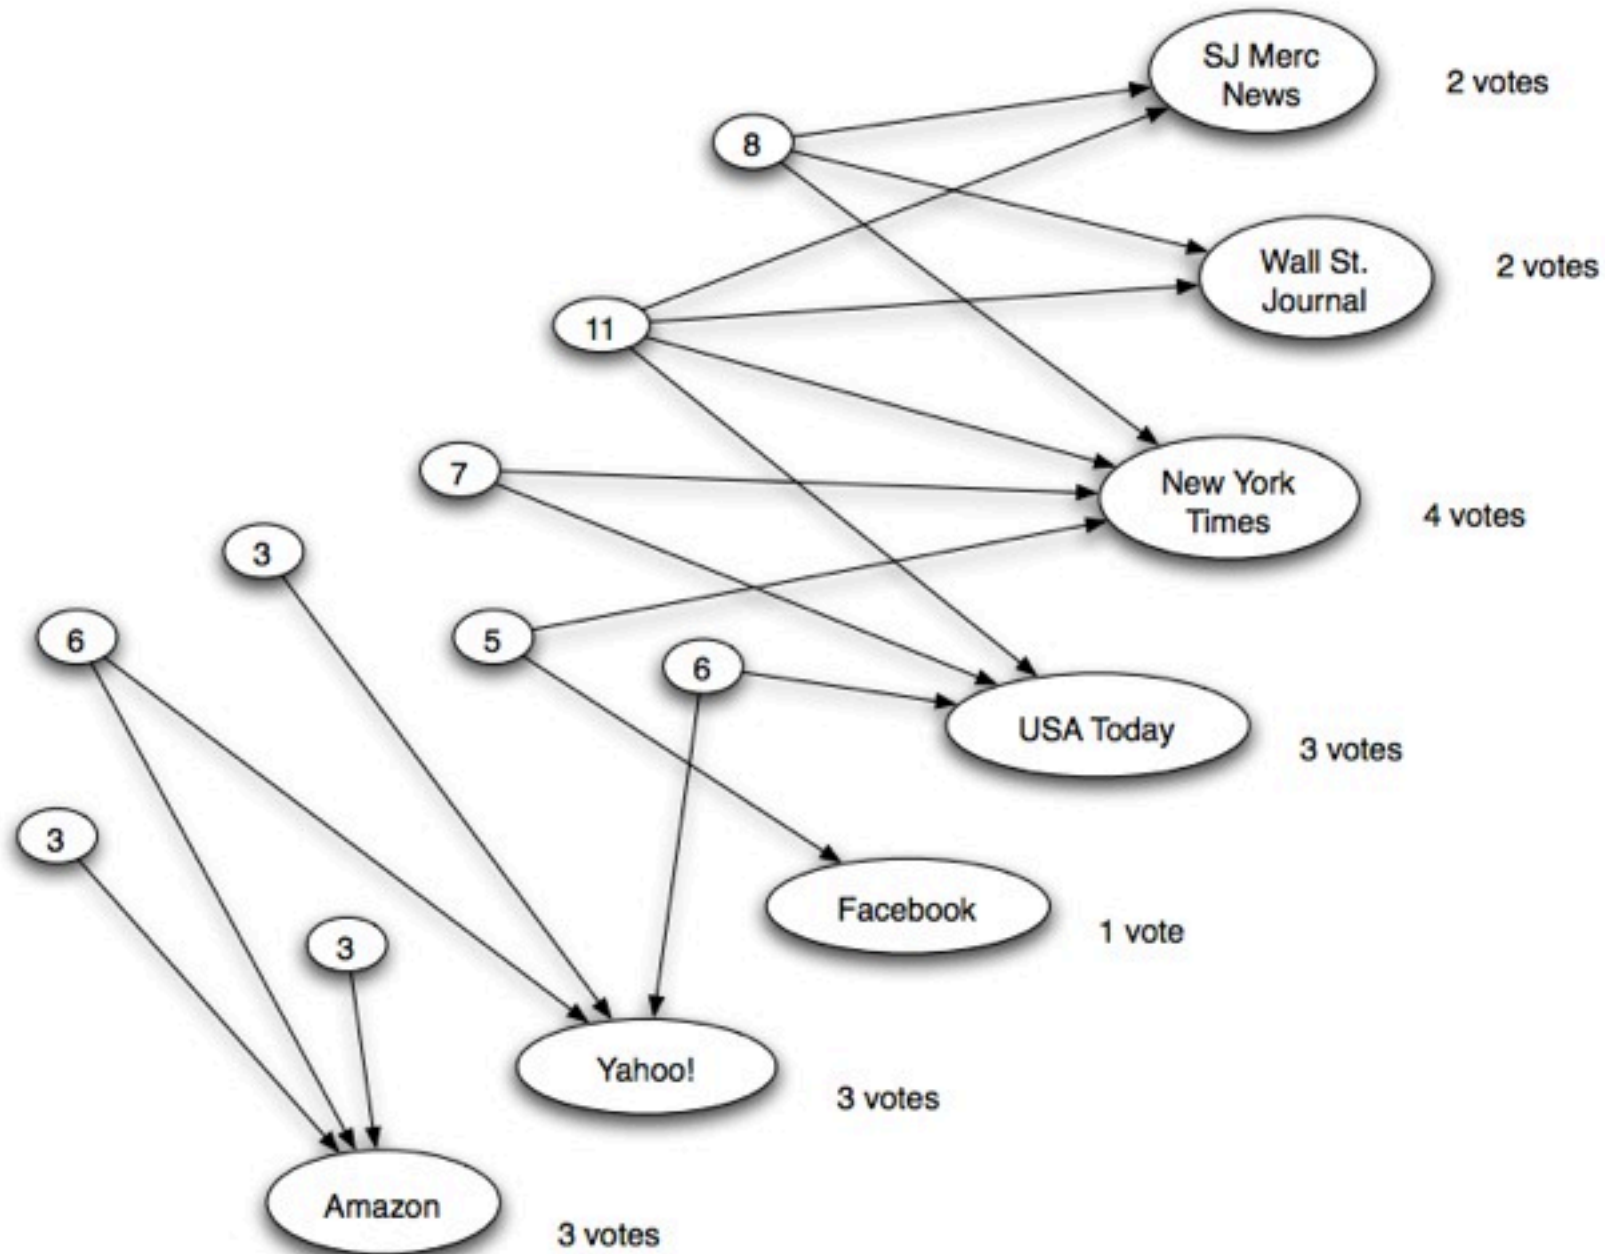

$$\lambda \pi^t \cdot A + (1 - \lambda) \pi_u = \pi^{t+1}$$

# Personalized Pagerank

- Equivalent random walk view
  - Easier to simulate via Monte-carlo

# HITS and SALSA

# More link prediction

- Pagerank -> personalized pagerank
- HITS -> SALSA
- Many other variants
  - Similar users
  - Simrank

# Scale

- A cautionary tale about scaling
  - Doing random walks
  - Weighted random walks
- Map-Reduce

# Uniform Random Walk

The key sampling routine:

- For a user, find a random following/follower, i.e. pick uniformly at random from  $[u_1, u_2, \dots, u_n]$

Budget per call: 20ms / 10K steps = 2000 ns /step

Main memory reference: 100 ns

Needs a call to random(), so just within budget

# Weighted Random Walk

But what if there are weights:

- For a user, find a random following/follower from  $[u_1, u_2, \dots, u_n]$  with weights  $[w_1, w_2, \dots, w_n]$

$n$  could be very large!

# Weighted Random Walk

Many simple ideas don't work:

- Pre-process + binary search:

$$[w_1 > w_2 > \dots > w_n]$$

Pay  $O(\log n)$  for every step

Cost for Obama: 20 comparisons + lookups

Recall: lookup is 100 ns, so out of budget :(

# Weighted Random Walk

We can do a lot better!

In fact, we can do it in  $O(1)$  lookups

2 random calls + 2 memory lookups!

Walker, Alastair J. (1974a), Fast Generation of Uniformly Distributed Pseudorandom Numbers With Floating Point Representation, Electronics Letters, 10, 553-554.

# The Walker Method

# The Walker Method

# The Walker Method

Central idea:

Equalize weights to  $\bar{w}$

# The Walker Method

Central idea:

Equalize weights to  $\bar{w}$   
(can be transitive)

# The Walker Method

Key observation:  
Never need to borrow  
weight from more than *one*

# The Walker Method

Lemma: Can equalize weights among any set of  $n$  elements such that each bin has at most two elements.

Proof by induction:

- Easy for two
- Suppose true for any set of  $n$  elements
- Pick an element below average and transfer weight from someone above average (now the latter can be below average)
- Now we are back to the  $n$  case!

# The Walker Method

For each  $i$ , we have:

$$(u_i, w_i, \text{Next}(u_i))$$

# The Walker Method

Algorithm:

1. Go to a random  $u_i$
2. Pick a random  $1 \leq x \leq \bar{w}$
3. If  $(x < w_i)$   
    return  $u_i$   
    else  
    return Next( $u_i$ )

# The Walker Method

2 random calls + 2 memory lookups!

Are we done?

Engineering:  $(u_i, w_i, \text{Next}(u_i))$

- $(\text{Int}, \text{Double}, \text{Int}) = (4+8+4)*15*10^9 \sim 240\text{GB}$
- Oops!

# Summary

- Network structure is information rich
- Lots of practical applications
- Many algorithmic challenges

# Thanks for listening!
